### ABSTRACT

Telangana is the twelfth maximum populous country in India in phrases of populace. Single-own circle of relative's houses are maximum typically called houses or houses. An condominium residence with a couple of housing devices is referred to as a two-own circle of relatives' residence or an condominium residence. Mansion is a resident-owned, non-condo condominium. The production area is of specific significance nowadays because of India's young populace and the resultant boom in housing demand. Land costs are skyrocketing because of growing housing demand. As a result, fabric costs also are growing. Limited homes and residing areas must additionally be considered. Every day, significant fee will increase because of inflation are impacting extra production costs. Optimization strategies are presently achieved with the aid of using fixing complicated mathematical necessary and differential equations. Structure weight-based optimization has many realistic benefits in all regions of the technology. In the sphere of civil engineering, weight-optimized additives are less expensive and clean to move to production sites. In this study, gadget studying optimizations have been advanced to optimize the load of the rebar taking into consideration factors of shape, size, and topology. This studies paper introduces gadget studying (ML) to optimize the price of designing and building the constructing potential of a specific home. Machine studying (ML) makes use of operations that mimic herbal evolutionary operations consisting of reproduction, crossover, and mutation to progressively enhance the answer of next populations and bring advanced progeny growth. Global seek method. In this work, a pc software has been advanced to boost the layout of strengthened concrete homes at minimum price. The plan consists of the appearance of the (ML) layout and the readiness of the goal feature. Then, with numerous constraints applied, the changed goal feature arrives. This will calculate the changed price of the required fabric. Concrete and reinforcement, and parametric studies are managed.

## INTRODUCTION

This paper offers a brand new optimization technique for the layout of bolstered concrete (RC) systems. Optimal sizing and reinforcement of columns in multi span and multi storey RC systems consists of highest quality stiffness correlations among structural elements, saving fees over conventional previous artwork layout solutions.

With all of the engineering necessities for designing beams, columns, slabs, and foundations with many suited pass sections, maximum engineers have the proper pass segment to reduce fees without similarly calculations. I have. Don't hesitate to pick out to increase. This report permits engineers to apply layout optimization fashions to effortlessly pick the proper dimensions for additives and reduce the value of concrete, steel, and systems.

Following latest tendencies within side the area of RC structural layout optimization during the last decades, many researchers have used mathematical and evolutionary seek strategies to optimize the layout as a characteristic of the aggregate of gravity and lateral load. I used it. I attempted it. Upon arrival, Krishnamurthy and Munro used linear programming to optimize the bolstered concrete frame. Originally advanced via way of means of Francis Galton, linear regression is extensively utilized in predictive analytics and Modelling. Once you already know the peak of someone, you could use equations to expect that person's weight. This instance predicts the load of someone whilst he's tall. This easy linear regression examines the impact of unbiased variables at the results. These researchers essentially set structural parameters consisting of cloth properties, boundary conditions, and structural length as inputs to the linear

regression version to expect the capacity of the shape to resist loads. Due to its significance withinside the industry, optimization of concrete systems has been the difficulty of a few preceding research. A thorough literature assessment in this difficulty is past the scope of this article, however a few wonderful optimization research are in brief stated here. For instance, Balling and Yao (1997) and Mohar Rami and Grierson (1993) used nonlinear programming (NLP) strategies in RC frames to realistically spherical non-stop values of beams, columns, and shear wall elements. Rice area. I changed into searching out a solution ordered via way of means of an order of magnitude.

This look at implements an set of rules that could generate value-optimized designs for RC systems primarily based totally on practical value facts for materials, modeling, and staff even as assembly all ACI 318 05 code and layout overall performance necessities increase. This optimization system is proven in a layout instance that examines the impact of stiffness distribution at the highest quality span of a portal frame, the highest quality quantity of columns for a selected span, and the highest quality length of a composite shape. gain. RS way concrete and stone value facts to get a sensible value relying on the scale of the structural element.

**Residential Building**

A dwelling is a detached house or a block of an apartment, or a building with or less on the 3rd floor or less above ground. However, when applied to a building within the boundaries of a municipality with a population of 1 million or more, "dwelling" means a building that includes dwelling units on the 4th floor or lower above the ground. Residents are mostly permanent.

Minimizing energy consumption and life cycle cost are two key factors in home construction. Therefore, in order to achieve the optimum shape with the best performance, we combined a new optimization simulation method called "Enhanced Emperor Penguin Optimizer" with a building energy simulation tool called "Quest" to minimize the energy consumption of the house. Suppress to. A comprehensive list of envelope criteria to consider.

In general, the model optimization process can reduce computational time and cost. Comparing the particle swarms, the applied method works very well and is very close to the optimal in less than 50% of the simulation. Population growth and increasing demand from the local economy for new buildings are considered to be the largest contributors to green house gas emissions. Therefore, improving the energy efficiency of the building sector has become an important goal not only for the construction of fossil fuels, but also for the reduction of gas emissions. One of the most effective approaches to reducing CO2 emissions and energy consumption in new buildings is to consider the energy efficiency of

**METHODOLOGY**

The machine learning optimization approach consists of applying three consecutive steps:

1. Use Energy Plus to build an energy model (basic model), sample input parameters and perform energy simulations. 2) Introduce simulated I / O

relationships when features / labels and models are incorporated into the ML algorithm. 3) Bayesian black box optimization to minimize the total power consumption of for the energy consumption of the building. Define design variables in the minimum- maximum range, run input samples with a uniform distribution, get a set of samples and Energy Plus input files, and create a database for training ML- based predictive models. Generated from the value. All of these files were then evaluated / simulated in Energy Plus. At this point, I used a custom Python script to automate both the process that generated the input file and the reading of the Energy Plus output file from the associated simulation run.

**Objective Function**

Minimized targeting functionality is calculated for identity tagging. This function calculates the total frame value. In addition to the unit price, it is expressed by the volume of concrete, the weight of steel, and the proximity of the formwork to the slab.

The total cost of a reinforced concrete airframe can be expressed as:

$$\text{Cost} = C_{\text{beam}} + C_{\text{column}} + C_{\text{slab}} + C_{\text{footing}}$$

$$C_{\text{columns}} = C_c n_c \sum_{i=1}^{N_s} (V_{cc} - V_{cs} - V_l)_i + C_s n_c \gamma_s \sum_{i=1}^{N_s} (V_{cs} + V_l)_i + C_l n_c \sum_{i=1}^{N_s} (A_{cl})_i$$

$$C_{\text{beams}} = C_c n_b \sum_{i=1}^{N_s} (V_{bc} - V_{bs} - V_v)_i + C_s n_b \gamma_s \sum_{i=1}^{N_s} (V_{bs} + V_v)_i + C_l n_b \sum_{i=1}^{N_s} (A_{bl})_i$$

$$C_{\text{slabs}} = C_c n_s \sum_{i=1}^{N_s} (V_{sc} - V_{ss} - V_l)_i + C_s n_s \gamma_s \sum_{i=1}^{N_s} (V_{ss} + V_l)_i + C_l n_s \sum_{i=1}^{N_s} (A_{sl})_i$$

$$C_{\text{footings}} = C_c n_f \sum_{i=1}^{N_s} (V_{fc} - V_{fs} - V_l)_i + C_s n_f \gamma_s \sum_{i=1}^{N_s} (V_{fs} + V_l)_i + C_l n_f \sum_{i=1}^{N_s} (A_{fl})_i$$

**Where**

Include accurate energy predictions for optimal decision making.

- C column = cost of column for the whole frame
- C beam = cost of beam for the whole frame
- C slab = cost of slab for the whole frame
- C footing = cost of footing for the whole frame
- C<sub>c</sub> = cost of concrete per unit volume.
- C<sub>s</sub> = cost of steel, ties, and stirrups per unit weight. C<sub>f</sub> = cost of framework per unit surface area.
- N<sub>s</sub> = numbers of stories
- N<sub>c</sub> = numbers of columns per story. N<sub>b</sub> = numbers of beams per story
- γ<sub>s</sub> = unit weight of steel.
- V<sub>cc</sub> = Volume of concrete in a column, calculated by using equation

$V_{cs}$  = Volume of longitudinal reinforced steel in a column, calculated by using equation.

$V_i$  = Volume of lateral ties in a column, calculated by using equation.

$A_{cl}$  = surface area of formwork for a column.

$V_{bc}$  = volume of concrete in a beam, calculated by using equation.

$V_{bs}$  = volume of tensile reinforced steel in a beam, calculated using equation.

$V_{ss}$  = volume of tensile reinforced steel in a slab, calculated using equation.

$V_{fs}$  = volume of tensile reinforced steel in a footing, calculated using equation.

$A_{bl}$  = surface area of framework for a beam

$A_{sl}$  = surface area of framework for a slab

$A_{fl}$  = surface area of framework for a footing

**General Description**

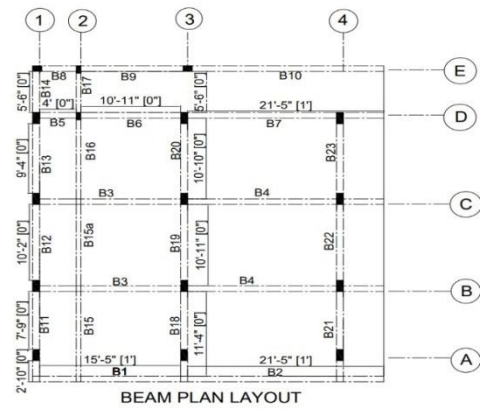

1. Type of Building – G +2 Residential Building
2. Number of storey - 2 Storey
3. Types of foundation – Shallow foundation
4. Height of building – 9m from G.L
5. Total gross area of the building – 138.88 sq.m
6. Column Size – 230 x 300 & 230 x 460 mm
7. Beam Size – 230 x 300 & 230 x 460 mm
8. Slab thickness – 150mm
9. Footing Size – 1220 x 1220 x 1000mm

**Design Criteria**

Concrete Grade: M20 N/mm<sup>2</sup>

Steel Grade: Fe 415 N/mm<sup>2</sup>

Overall depth Slab: 150mm

**Dead loads**

Unit Weight of the Concrete: 25 KN/m<sup>3</sup>

Unit Weight of the Brick: 20 KN/m<sup>3</sup>

Self-weight of the Beam: 2.97 KN/m Self-weight of the Column: 0.793 KN/m Self-weight of the Slab: 6.192 KN/m

Floor Finish: 1 KN/m<sup>2</sup>

**Live loads**

For Residential Building: 2 KN/m<sup>2</sup>

## Design of Slabs

### Given data

Effective Shorter Span ( $L_x$ ) = 2.103m Effective Longer Span ( $L_y$ ) = 3.84m Width of Support = 0.23m  
 $f_{ck}$  = 20 N/mm<sup>2</sup>  
 $f_y$  = 415 N/mm<sup>2</sup>

### Step 1: Type of Slab:

$L_y/L_x = 3.84/2.103$   
 $= 1.82 < 2$   
 Since  $L_y/L_x$  ratio is lesser than 2  
 The slab should be designed as two-way Slab

### Step 2: Depth of Slabs

Clear cover = 25 mm  
 Adopt effective depth ( $d$ ) = 125mm  
 Over all depth ( $D$ ) = 150mm

### Step 3: Loads

Self-weight of slab = 6.192 KN/m<sup>2</sup>  
 Live load = 2 KN/m<sup>2</sup>  
 Floor finish = 1 KN/m<sup>2</sup>  
 Total load = 9.192 KN/m<sup>2</sup>  
 Factored load ( $W_u$ ) = (1.5 X 6.192) = 9.288 KN/m<sup>2</sup>

### Step 4: Maximum Bending Moment

From IS 456, Table 26  
 Short span coefficient  
 $\alpha_x$  (-ve) = 0.0418  
 $\alpha_x$  (+ve) = 0.0312  
 Long span coefficient  
 $\alpha_y$  (-ve) = 0.032  
 $\alpha_y$  (+ve) = 0.024  
 $M_{ux(+ve)} = \alpha_x W_l x^2 = (0.0418 \times 9.288 \times 2.103) = 0.816$  KN-m  
 $M_{ux(-ve)} = \alpha_x W_l x^2 = (0.0312 \times 9.288 \times 2.103) = 0.609$  KN-m  
 $M_{uy(+ve)} = \alpha_y W_l x^2 = (0.024 \times 9.288 \times 2.103) = 0.468$  KN-m  
 $M_{uy(-ve)} = \alpha_y W_l x^2 = (0.032 \times 9.288 \times 2.103) = 0.625$  KN-m

### Step 5: Check for depth

From IS 456, Pg.no:96  
 $M_u.lim = 0.36 X_{u,max}/d (1 - 0.42 X_{u,max}/d) b d^2 f_{ck}$   
 $= 0.36 \times 0.48 \times (1 - (0.42 \times 0.48)) \times 1000 \times (125)^2 \times 20$   
 $M_u, lim = 43.11 \times 10^6$  KN-m  
 $M_u, actual < M_u, lim$   
 Hence section is under reinforced Hence safe

### Step 6: Calculations of Reinforcement

#### Shorter Span

$M_u = 0.87 f_y A_{st} x d (1 - A_{st} f_y b d f_{ck})$   
 $0.816 \times 10^6 = 0.87 \times 415 \times A_{st} \times 125 \times (1 - A_{st} \times 415 \times 1000 \times 125 \times 20)$   
 $A_{st, Req} = 481.92$  mm<sup>2</sup>

Use 10mm  $\phi$  bars,  
 $S_v = 50.26/481.92 \times 1000$   
 $S_v = 104.29$  mm  
 Provide 8mm  $\phi$  bars @104mm/c  
 $A_{st, prov} = 120$  mm<sup>2</sup>

#### Longer Span

$M_u = 0.87 f_y A_{st} d (1 - A_{st} f_y b d f_{ck})$   
 $0.468 \times 10^6 = 0.87 \times 415 \times A_{st} \times 125 \times (1 - A_{st} \times 415 \times 1000 \times 125 \times 20)$   
 $A_{st} = 481.92$  mm<sup>2</sup>  
 Use 10mm  $\phi$  bars,  
 $S_v = 50.26/481.92 \times 1000$   
 $= 104.29$  mm  
 Provide 8mm  $\phi$  bars @ 104 mm/c  
 $A_{st, prov} = 120$  mm<sup>2</sup>

## Design of Beams

### Step 1: Given Data

Effective Length = 11.26 m Width = 230 mm

Depth = 435 mm  
 Cover = 25 mm  
 $D = 460$  mm  
 Grade of Concrete = M20  
 Grade of Steel = Fe415  
 $= 250$  mm  
 Provide 4 nos. of 16 mm dia. bars @ 250 mm c/c

### Step 6: Check for shear

$V_u = 89.61$  KN  
 $\tau_v = V_u/b \times d = 24389/230 \times 435$   
 $= 0.243$  N / mm<sup>2</sup>  
 $\tau_c = 0.4$  N / mm<sup>2</sup>,  $\tau_c \max = 2.8$  N / mm<sup>2</sup>  $\tau_c \max > \tau_c > \tau_v$   
 Shear Reinforcement should be provided.  
 $V_{us} = 0.87 \times f_y \times A_{sv} \times d / S_v$   
 $S_v = 0.87 \times 415 \times 250 \times 435 / 89.61 \times 10^3 = 438$  mm Provide 10mm dia. of 2 Legged Stirrups @ 400 mm c/c

### Step 7: Check for Spacing

$S_v \leq (0.75 d) = 0.75 \times 435 = 326$  mm  
 $S_v \leq (A_{sv} \times f_y / 0.4 \times b)$   
 $S_v = (250 \times 415 / 0.4 \times 230) = 1127$  mm  
 $S_v \leq 300$  mm  
 Hence ok

## Design of Columns

Use M20 grade Concrete and FE415 grade Steel. Length,  $L = 3$  m  
 Size = 460 x 230 mm & 300 x 230 mm

### Step 2: Load Calculations

Dead Load from slab = 1 KN / m<sup>2</sup>  
 Wall Load = 0.23 x 20 x 3 = 13.8 KN/m  
 Self-Weight of beam = 0.23 x 0.435 x 25 = 2.5 KN/m  
 Live Load = 2 KN/m  
 Total Dead Load ( $W_d$ ) = 21.66 KN/m

### Step 3: Ultimate Bending moment and Shear

$M_u \text{ support} = 1.5 \times (W_d \times l^2) / 12$   
 $= 1.5 \times (21.66 \times (11.26)^2) / 12$   
 $= 343.27$  KN-m

**Step 4: Check for Depth**

$$d = \sqrt{M_u / (0.136 \times f_{ck} \times b)}$$

$$= \sqrt{343.27 \times 10^6 / (0.136 \times 20 \times 230)}$$

$$= 740 \text{ mm } d_{\text{provided}} > d_{\text{required}}$$

Hence OK

**Step 5: Area of Steel**

At Support

$$C_{\text{min}} = \frac{500}{100} = 5$$

$$\text{Load} = 1200 \text{ KN}$$

$$\text{Factored load} = 1.5 \times 1200 = 1800 \text{ KN}$$

**Step 1: Calculation of Ac**

By assuming % of Steel as 1% of cross area

$$A_{sc} = 1/100 \times A_g = 0.01 A_g$$

$$A_g = A_{sc} + A_c \quad A_c = A_g - A_{sc} \quad A_c = 0.99 A_g$$

**Step 2: Calculation of Dimensions of Column**

$$P_u = 0.45 f_{ck} A_c + 0.67 f_u A_{sc}$$

$$1200 \times 10^3 = 0.45 \times 20 \times 0.99 A_g + 0.67 \times 415 \times 0.01 A_g$$

$$A_g = 153971.173 \text{ mm}^2$$

By using Rectangular Column with Area of  $a^2$

$$A^2 = 153971.173 \text{ mm}^2$$

$$A = 392 \text{ mm}$$

Take a as 400 mm

$$E_{\text{min}} = \frac{3500}{f_{ck}} + \frac{400}{f_u} \geq 20$$

Hence Safe

**Step 3: Calculations of Area of main steel Ac**

$$P_u = 0.4 f_{ck} A_c + 0.67 f_u A_{sc}$$

$$A_g = A_c + A_{sc}$$

$$A_c = A_g - A_{sc}$$

$$1800 \times 10^3 = 0.4 \times 20 \times (153971.173 - A_{sc}) + 0.67 \times 415 \times A_{sc}$$

$$A_{sc} = 153.711 \text{ mm}^2$$

$$\text{Take } 1540 \text{ mm}^2$$

By taking 16 mm dia bars

$$1 \text{ bar} = \frac{\pi}{4} \times (16)^2 = 201 \text{ mm}^2$$

$$\text{Numbers of bars} = 1540 / 201 = 7.66$$

So, take 8 bars of 16 mm dia bar

**Step 4: Calculation of transverse reinforcement**

$$16 d = 16 \times 16 = 256 \text{ mm}$$

Min lateral dimensions = 400 mm

300mm

So, c/c distance between ties 256mm

Dia of bar

$$0.25 \times d = 0.25 \times 16 = 4 \text{ mm}$$

5 mm

So, take 8 mm dia bar

Final reinforcement use 8 bars of 16mm dia main and 8 bars of 250 mm distance ties.

**Design of Footing**

**Given Data**

Size of the column = 230x460mm Load on the column  $W_u = 263.5 \text{ KN}$  Safe bearing capacity of soil,  $q_0 = 571.08 \text{ KN/mm}^2$   
 $f_{ck} = 20 \text{ N/mm}^2$   $f_y = 415 \text{ N/mm}^2$

**Step 1: Size of footing**

Load on column = 263.5 KN

10 % of column axial

Load for footing = 10% (263.5)

$$= 263.5 + 160$$

$$= 423.5 \text{ KN}$$

Area of footing = load on footing / SBC

$$= 423.5 / 200$$

$$= 2.1 \text{ m}$$

So, we can take 2.1 x 2.1 m

**Step 2 Net upward pressure Stress = force / area**

= 1.5 x total load on footing / area of footing

$$= 1.5 \times 423.5 / 2.1 \times 2.1$$

$$= 144.04 \text{ KN/m}^2$$

**Step 3 Bending moment**

@critical section of the footing critical section @

Force of column from the edge of column

$$2100/2 - 230/2 = 935 \text{ mm}$$

Load on critical section = stress x bf

$$= 144.04 \times 230$$

$$= 302.5 \text{ KN/m}$$

$$\text{Bending moment} = Wl^2 / 2 = 302.5 \times (0.82)^2 / 2$$

$$= 124.025 \text{ KN.m}$$

$$1800 \times 10^3 = 0.4 \times 20 \times (153971.173 - A_{sc}) + 0.67 \times 415 \times A_{sc}$$

$$A_{sc} = 153.711 \text{ mm}^2$$

$$\text{Take } 1540 \text{ mm}^2$$

$$\text{By taking } 16 \text{ mm dia bars}$$

1 bar =  $\pi/4 \times (16)^2 = 201 \text{ mm}^2$

$$\text{Numbers of bars} = 1540 / 201 = 7.66$$

$$\text{So, take 8 bars of 16 mm dia bar}$$

So, take 8 bars of 16 mm dia bar

**Step 4 Calculation of transverse reinforcement**

$$16 d = 16 \times 16 = 256 \text{ mm}$$

Min lateral dimensions = 400 mm

300mm

So, c/c distance between ties 256mm

Dia of bar

$$0.25 \times d = 0.25 \times 16 = 4 \text{ mm}$$

5 mm

So, take 8 mm dia bar

Final reinforcement use 8 bars of 16mm dia main and 8 bars of 250 mm distance ties.

**Design of Footing**

**Given Data**

Size of the column = 230x460mm Load on the column  $W_u = 263.5 \text{ KN}$  Safe bearing capacity of soil,  $q_0 = 571.08 \text{ KN/mm}^2$   
 $f_{ck} = 20 \text{ N/mm}^2$   $f_y = 415 \text{ N/mm}^2$

**Step 1: Size of footing**

Load on column = 263.5 KN

10 % of column axial

load for footing = 10% (263.5)  
 = 263.5 +160  
 = 423.5 KN  
 Area of footing = load on footing / SBC  
 = 423.5 / 200  
 = 2.1 m  
 So, we can take 2.1 x 2.1 m

**Step 2: Net upward pressure**

Stress = force / area  
 = 1.5 x total load on footing / area of footing  
 = 1.5 x 423.5 / 2.1 x 2.1  
 = 144.04KN /m2

**Step 3: Bending moment**

@critical section of the footing critical section @  
 force of column from the edge of column  
 2100/2 – 230 /2 = 935 mm  
 Load on critical section = stress x bf  
 = 144.04 x 230  
 = 302.5 KN /m  
 Bending moment =  $Wl^2 / 2 = 302.5 \times (0.82)^2 / 2$   
 = 124.025 KN.m

**Estimation**

**Table 1** Estimation

S.NO	Description	Quantity	Amount
1	Earthwork Excavation	96 Ft	1,24,800

**Machine learning model**

The model's parameters are the constituent variables inside the model, and their values can be estimated from the specified data.

- Requirements in the model for prediction.
- There is a function in the problem definition model.
- You are estimated or learned from the data.
- In many cases, prediction is not set manually.
- Usually saved as part of a trained model

Therefore, point-to-point are important parameters for machine learning algorithms. This is also part of model learned from past training data. The specific models used in machine learning are the functions and parameters needed to make predictions for new data. Whether a model has fixed parameters or variables determines whether the model can be said to be parametric or non-parametric.

**Machine Learning**

Machine learning (ML) is a type of artificial intelligence (AI) that allows you to predict outcomes more accurately, even if your software application is not explicitly programmed. Thus, machine learning algorithms use historical data as input to predict new output values. Recommended motor is a general use case for the machine study. Other popular uses include fraud detection, spam filtering, malware threat detection, business process automation, and predictive maintenance. Machine learning is important because it provides companies with an overview of customer behaviour trends and operates samples to aid in new product development. Many large companies today, such as Facebook, Google, and Uber, have machine learning technology at the core of their business. Machine learning has become an important competitive factor for many companies.

In statistical Modelling, regression analysis is a set of statistical procedures for estimating the relationship between a dependent variable and one or more independent variables. The most common form of regression analysis is linear regression, where one finds the line that best fits the data according to a particular mathematical criterion. First, regression analysis is widely used for prediction and forecasting, where its use overlaps significantly with the field of machine learning. Second, in some cases, regression analysis can be used to infer a causal relationship between independent and dependent variables.

XG Boost is a synthetic machine learning algorithm based on a decision tree using a scoring framework. In prediction problems involving unstructured data, artificial neural networks tend to outperform all other algorithms or frameworks. XG Boost stands for Extreme Grading Boosting. It uses more precise approximations to find the best tree model. Boost: N new training datasets are formed by replacing random sampling from the original data set, where some observations can be repeated in each new training dataset.

**RESULTS AND DISCUSSIONS**

The obtained optimization results are illustrated for different groups of beams, columns, floors and foundations. They are also represented as numbers. ML optimization results are confirmed with manual design values for all groups of all individual components.

**CONCLUSION**

The Following Conclusions can be drawn from this Study.

1. A two-story frame consisting of beams, columns, floors and foundations has been successfully optimized using ML optimization.
2. Optimized two-stage design including code specification IS-456:2000.
3. This study shows that heuristic methods and machine learning optimization tools are effective for optimized design of RC frameworks.

4. The variables used to obtain the optimal design are the effective depth and reinforcement area of beams, columns, slabs and foundations.
5. Results obtained by ML optimization have been verified by comparing with results obtained by manual calculation. The optimization results obtained for the reinforcement region of the element correspond exactly to the values obtained by manual calculation. From this, we can conclude that the design obtained by the proposed method is safe and economical.
6. The cost variation of the frame depending on the type of concrete was studied and found to be the smallest. M20 concrete type deviations are observed. And steel grade is used for Fe415.
7. We have studied the comparison between optimization results and AutoCAD design results. It has been found that the reduction in depth for beams and reinforcement can be up to 25%, compared to more than 50% for columns.
8. Cost comparison is a manual result. We found that we were able to reduce beams by 7.5% and columns by 45%. The optimized result has reduced the overall cost of the frame by 17%.
