Autism Spectrum Disorder, Early Childhood Education, Early Diagnosis.

ABSTRACT

Aim: The aim of this study was to investigate whether early childhood teachers can contribute to the early diagnosis of Autistic Spectrum Disorder (ASD). This disorder of neurodevelopment arises in the first years of life, characterized by a dyad that involves communication and consequent socialization and on the other hand the presence of repetitive and stereotyped behaviors with repertoire of interests and restricted activities (DSM-5, 2013). In this sense it is necessary to emphasize the pedagogical view of the teachers that attend this age group in which one can observe early characteristics of ASD. To know about the experience of these teachers with Early Childhood Education and with students with ASD, we know the characteristics of the disorder, evaluated by levels of training. **Method:** 300 teachers from the municipal network of Paulínia, Sao Paulo, Brazil; participated in the research through a specific questionnaire prepared for this purpose. **Results:** it was evidenced that teachers showed knowledge of the main characteristics of the picture, many students are in the stage of oral language acquisition and atypical characteristics can be observed by teachers. The working time of the interviewed teachers is between 5 and 15 years old or more. Many said they had worked with students with this disorder, pointed out as more important aspects the presence of expert teachers and school with resource rooms with materials adapted to receive these children. **Conclusion:** with this study it was possible to show that there is a lack of continuous training for teachers, teaching materials and adapted rooms. It should also be noted that if the diagnosis is made in the first 3 years (chronological age in which children are in preschool centers) and with early and long term interventions, there will be a positive impact on the prognosis of the cases.

INTRODUCTION

Autistic Spectrum Disorder (ASD) is classified according to the diagnostic criteria of the fifth edition of The Diagnostic and Statistical Manual of Mental Disorders DSM-5(2013) as a neurodevelopmental disorder. This disorder is characterized by a dyad that involves communication and consequent socialization and on the other hand the presence of repetitive and stereotyped behaviors with repertoire of interests and restricted activities DSM-5 (2013). Although the etiology is still unknown, several studies have shown evidence of associated epigenetic components, such as the interaction of genes and environment, Rutter (2011) as exposure to chemical components during gestation, Arif *et al* (2013). This disorder may be present since the 18-month Chronological Age, Charman (2014) and there are no biological markers for

this pathology Gadia *et al* (2004), the diagnosis depends on clinical and interdisciplinary observation Muszcat *et al*. (2014). The prevalence of the disorder is increasing, but it is discussed to what extent this expansion of the diagnostic criteria in DSM-5 occurs, the methodological differences in the scientific studies better recognition of the disorder by health professionals or whether there is a real increase in frequency (APA, 2013).

Recent data indicate an approximate prevalence of ASD from 0.60% to 1% in live newborns. Data from the Centers for Disease Control and Prevention (CDC) point to 1:68 North American live births. In Brazil an epidemiological study found a prevalence of 1 to 368 children aged 7 to 12 years Paula *et al* (2011) a study published by the CDC in 2014, points to 1:45 in the United States, the age group surveyed is 3 to 17 years. In this sense, it should be emphasized that in the age group in which early characteristics of TEA can be observed, children are already in full-time school and are in

the stage of oral language acquisition and many characteristics can be observed by teachers. In verbal or non-verbal communication, there are children who have difficulty initiating a conversation or looking in the eye, can have repetitive speech, no context, with a monotone voice, speech delay or regression, do not seem to hear or understand what is being said. There are children with ASD who perceive small details, such as the changing place of classroom objects, scents and textures, there are those who assemble jigsaw puzzles with impressive dexterity, and there are others with obsessive ways of playing, such as spinning objects, stack, load.

The Autism Diagnostic Observation Schedule-General (ADOS-G).

Recent data indicate an approximate prevalence of ASD from 0.60% to 1% in live newborns. Data from the Centers for Disease Control and Prevention (CDC) point to 1:68 North American live births. In Brazil an epidemiological study found a prevalence of 1 to 368 children aged 7 to 12 years Paula *et al* (2011) and a study published by the CDC in 2014, points to 1:45 in the United States, the age group surveyed is from 3 to 17 years. In this sense, it should be emphasized that in the age group in which early characteristics of ASD can be observed, children are already in full-time school and are in the stage of oral language acquisition and many characteristics can be observed by teachers. In verbal or non-verbal communication, there are children who have difficulty initiating a conversation or looking in the eye, can have repetitive speech, no context, with a monotone voice, speech delay or regression, do not seem to hear or understand what is being said.

Autistics have great resistance to change, including activities proposed by teachers, places of the room or school, changes in time. The lack of social reciprocity is evidenced by solitary play and improper use of toys, students with ASD do not understand the rules of proposed activities, do not play "pretend", do not understand contexts by facial expressions, Theory of Mind, Frith (1996), stereotypies vary from the flapping movement to complex rituals, Rappin (1997). For the diagnosis of ASD there is a screening instrument frequently used, Checklist for Autism in Toddlers (CHAT), for screening children 16 to 30 months of age, Baron-Cohen *et al*, 1992). The test is composed of 23 questions that explore the presence of developmental milestones (Baron-Cohen *et al*. 1996) The Childhood Autism Rating Scale (CARS) is for children older than two years and assesses the intensity of autistic characteristics and there is a way to differentiate children with developmental delay without autism. It has been translated and validated for use in Brazil and its final version is known as CARS-BR, Pereira *et al* (2008); Rapin *et al*. (2008). Two new tools have emerged to define the diagnosis of autism that are used mainly in the context of scientific research, namely: The Autism Diagnostic Interview-Revised (ADI-R) and also

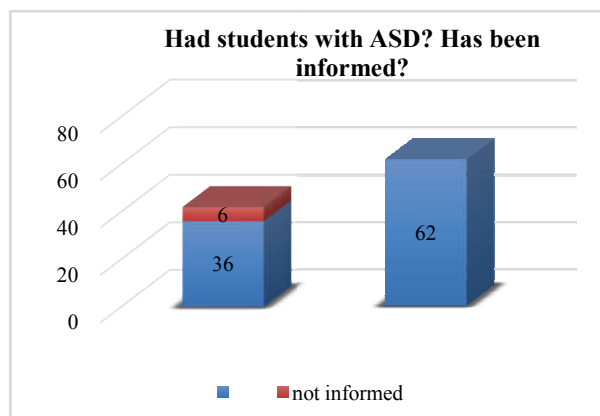

Figure 3

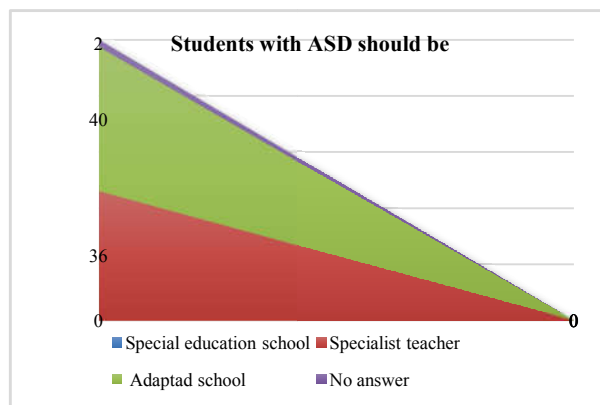

Figure 4

There are children with ASD who perceive small details, such as the changing place of classroom objects, scents and textures, there are those who assemble jigsaw puzzles with impressive dexterity, and there are others with obsessive ways of playing, such as spinning objects, stack, load. Autistics have great resistance to change, including activities proposed by teachers, places in the classroom or school, changes in time. The lack of social reciprocity is evidenced by solitary play and improper use of toys, students with ASD do not understand the rules of proposed activities, do not play "pretend", do not understand contexts by facial expressions, theory of mind, Frith (1996), stereotypies vary from the flapping movement to complex rituals, Rappin (1997). For the

diagnosis of ASD there is a screening instrument often used, Checklist for Autism in Toddlers (CHAT) for the screening of children aged 16 to 30 months, Baron-Cohen *et al* (1992). The test is composed of 23 questions that explore the presence of developmental milestones, Baron-Cohen *et al.* (1996).

The Childhood Autism Rating Scale (CARS) is for children older than two years and assesses the intensity of autistic characteristics and there is how to differentiate children with developmental delay without autism. It has been translated and validated for use in Brazil and its final version is known as CARS-BR Pereira *et al* (2008); Rapin *et al.* (2008). Two new tools have emerged to define the diagnosis of autism that are used mainly in the context of scientific research, namely: The Autism Diagnostic Interview-Revised (ADI-R) and also The Autism Diagnostic Observation Schedule-General (ADOS-G). The main comorbidities of ASD are: Intellectual disability (70-86% of cases of ASD); ADHD (37-85%); epilepsy (35%); eating disorders; genetic syndromes; oppositional-defiant disorder; disorder of coordination development; mood disorder (20%); tics; schizophrenia, conduct disorder; obsessive compulsive disorder OCD; enuresis; encoprese; disorder sleep (40 to 80%); post-traumatic stress syndrome; anxiety disorder (30 to 84%); Tourette's syndrome; psychosis, Schwartzman (2011), Rotta *et al* (2016).

Early identification of ASD in children in the early childhood education stage brings benefits to the child and the family. This includes correct diagnosis, pedagogical support, behavioral and communication oriented interventions, as well as treatment of comorbidities, Dover, Couteur (2006). In order to have a positive impact on the prognosis regarding psychosocial and family adaptation, cognitive performance, adaptive behavior and communication and social interaction skills Virués-Ortega (2010), when social and academic demands have a greater influence on the life of this child. For Vigotsky (2007) the school needs to create tools that can guarantee the full development of any individual, with or without disabilities. In this perspective, it is essential that it knows the mental processes of the subjects in / for the construction of objectives and / or educational programs, capable of potentializing their cognitive functions, Vigotsky, (2007). In this way, as many teachers work with children without the diagnosis of ASD, this was the motivation to investigate the importance of early childhood education teachers in the early diagnosis.

METHOD

Sample and procedure

300 teachers from the public schools of the city of Paulínia, Sao Paulo, Brazil, were invited. The project was submitted to the Human Research Ethics Committee (CEP) of the School of Medical Sciences of the University of Campinas-UNICAMP, pursuant to resolution 466/12, approved with the opinion no. 1,278,180, the beginning of the after the approval of said council. The participation of the teachers was voluntary, through a questionnaire developed exclusively for this purpose, with 2 open and 10 closed questions. Teachers with a high school degree in Teaching, Pedagogues and graduates in the area of Education were participants.

RESULTS

Of the 300 professors invited to participate in research 98 agreed on respond to the questionnaire, signed the Informed Consent Term. Statistical analysis of the data was done using the Chi-Square, Fisher's Exact Test (TEF) for comparison between groups. The level of significance between groups was $p = 0.01$ and the open multiple choice questions were analyzed by the Statistics 21.0 for Windows® Statistical Package for Social Sciences (SPSS) worksheet.

DISCUSSION

The results show a frequency of 100% of women working in the units surveyed. A study in Sao Paulo with teachers from regular and special schools showed the perspective of teachers with children and adolescents with ASD in the classroom, lack of knowledge, lack of support from other professionals, Pimentel *et al.* (2014). In addition there is no continuing education. In this research more than 80% of the graduate professors count that they looked for in the specialization a way to improve the pedagogical practice. There are no content adequacy study groups to welcome students with any type of disorder or disability. A work done by Spanish researchers point similar information about the importance of the teacher in the early diagnosis Rodriguez *et al* (2012). In the United States, research indicates that the states where the diagnosis is most precocious are those that invest most in Education and Health. In the interior of Sao Paulo, work similar to this one, evaluated the teaching experience with children with ASD in the work of 38 teachers. They concluded that these were lacking in information and pointed out the need for diffusion of knowledge for teachers with the help of other professionals, Favoretto *et al* (2014).

Doubts about ASD and Education are not unique to Brazilian Education, in other countries there is also a lack of teacher knowledge about autism. A study in Pakistan about the lack of unknowledge of Early Childhood Teachers about ASD showed that there was a marked improvement in the school performance of students of teachers trained by a manual of resources for teachers dealing with autism. The study emphasizes that adequate teacher training can improve the quality of work with these students. There are proposals for the implementation of diagnostic training programs so that teachers can teach the students according to their needs. In the present study, educator training was seen as important for dealing with students with ASD. However, in spite of this, no significant difference was found between the degree of training and the fact that she felt prepared to deal with students with this disorder, even though she had more time to work with these students. The need to expand and update knowledge about the disorder, exchanges of information and experiences among teachers of the regular network has been evidenced, this supports the idea that theoretical and practical knowledge is necessary for the work, Rodrigues *et al* (2012). Such data are in agreement with those observed in this research, where similar difficulties were observed in the work with ASD, does not depend on the level of teacher training. Although graduate teachers continue to feel unprepared to deal with ADS, it has changed the way they observe such children differently from others. For these teachers the great challenge in these frameworks is how to aid in early diagnosis. Although many of the teachers are knowledgeable about autism, even with recognized professional skills, most

feel unprepared for working with students with ASD. Training and working time did not influence, in the present sample, the aspects that they consider important to work with. In this way it can be inferred that the classroom experience with students with ASD is what prepares them for such a challenge. Thus, exchange of experiences, study groups, expert technical guidance for the classroom. All this forms a body that transmits security to the teacher who often perceives changes in behavior in his students, therefore, can aid in diagnosis and intervention precocious. This research brings light to some demands, but further studies are needed to expand knowledge. If the diagnosis is made in the first 3 years (the age at which the children are in the kinderarten) and with early and long-term interventions, there will be a positive impact on the prognosis, as well as on the family, social and psychological adaptation to cognitive and to adaptive behavior, in communication skills and social interaction Virués-Ortega (2010).

CONCLUSION

We can conclude that if children attend kindergarten at the age at which it is possible to make an early diagnosis of ASD, it is necessary to have continuous training for the preparation of teachers who receive these students together with other professionals, therefore, despite teachers of Early Childhood Education when their students have atypical development can not point to it and do not participate in early diagnosis. Exchanges of experiences and study groups should involve teachers who are able to point out the neurodevelopmental problems of their students. It is necessary to expand studies and knowledge.
